The trapezoidal map of non-crossing line segments

Problem: Polygon Triangulation

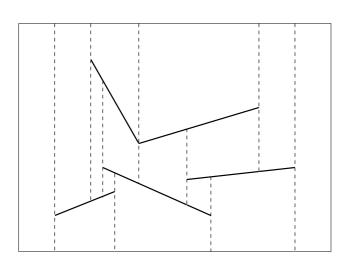

Given a simple polygon  ${\cal P}$  with n edges, compute a triangulation of its interior.

2

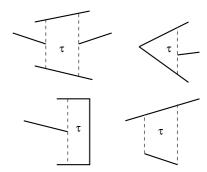

# Solution via Trapezoidal Map

Given a set S of n nonintersecting segments in the plane, compute its  $trapezoidal\ map$ .

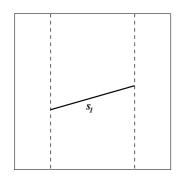

## Trapezoidal Map

- ullet planar graph, vertices V, edges E, faces F
- ullet V: endpoints, artificial vertices
- E: pieces of segments, vertical extensions
- F: set of *trapezoids*, each one incident to at most 4 segments (assuming no two endpoints have the same x-coordinate)

# Randomized Incremental Construction

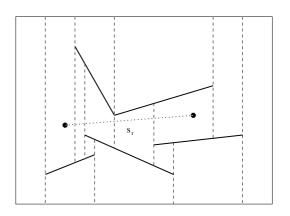

1. Compute trapezoidal map of  $\{s_1\}\mapsto T_1$ 

2. Insert segments  $s_2,\ldots,s_n$  in random order  $\mapsto T_n$ 

From  $T_{r-1}$  to  $T_r$  (I)

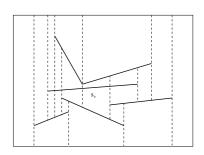

Find

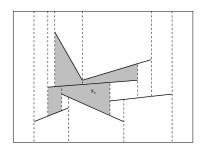

6

From  $T_{r-1}$  to  $T_r$  (II)

**Split** 

Merge

From  $\mathit{T}_{r-1}$  to  $\mathit{T}_{r}$  (III)

1. Find: Find the trapezoid containing the left endpoint of  $s_r$ 

2. **Split:** Trace  $s_r$  through  $T_{r-1}$  and split all the trapezoids intersected by  $s_r$ 

3. Merge: Remove parts of vertical extensions "cut off" by  $s_r$  and merge the adjacent trapezoids

7

5

# RIC - Analysis (I)

Apply configuration spaces!

- X: the set S of segments
- ullet  $\Pi$ : set of all trapezoids  $\Box$  defined by segments of S
- $D(\Box)$ : the (at most 4) segments incident to the trapezoid  $\Box$
- $K(\square)$ : the set of segments intersecting  $\square$

9

# Analysis of Update $T_{r-1} \mapsto T_r$ (I)

**Observation:** The number of trapezoids created by **Split** is at most twice as large as the number of new trapezoids in  $T_r$ .

**Proof:** For every **Merge** operation above (below)  $s_r$ , one new trapezoid below (above)  $s_r$  survives. It follows that at most half of the previously created trapezoids are not in  $T_r$ .

 $\Rightarrow$  Complexity of **Split** and **Merge** is  $O(|\{\Box \mid \Box \in T_r \setminus T_{r-1}\}|) = O(\deg(s_r, T_r)).$ 

### RIC – Analysis (II)

Cost of step  $T_{r-1} \mapsto T_r$ :

- Find: we'll care for that later...
- **Split**: constant time per traced □; □ is replaced by at most 4 new trapezoids.

- $\Rightarrow$  O(number of removed trapezoids)
- $\Rightarrow$  O(number of created trapezoids)
- Merge: O(number of trapezoids created in step Split)

10

Analysis of Update  $T_{r-1} \mapsto T_r$  (II)

Configuration Spaces  $\Rightarrow$  expected value of  $\deg(s_r, T_r)$  is  $\leq \frac{4}{r}E(|T_r|)$ .

- $|T_r| = O(r)$  (Exercise)
- Expected update cost  $T_{r-1} \mapsto T_r$  is O(1)
- ullet Overall expected update cost is O(n)

## Realization of Find

- History approach: store all the trapezoids of  $T_r, r=1\dots n$ .  $\square \in T_{r-1}\setminus T_r$  has pointers to all  $\square' \in T_r \setminus T_{r-1}$  with  $\square \cap \square' \neq \emptyset$
- At most 4 pointers per □
- Location of segment endpoint  $p_r$  of  $s_r$ : trace  $p_r$  through the history graph

Analysis of **Find** (I)

Assume  $p_r$  runs through a trapezoid  $\square$  different from the bounding box. Then there is  $j \leq r$  such that  $\square$  is child of some  $\square'$  with

- $\Box' \in T_{j-1} \setminus T_j$
- $s_r$  intersects  $\square'$
- $\Rightarrow$  length of history path to  $p_r$

$$\leq 1 + \sum_{j=1}^{r} \sum_{\square \in T_{j-1} \setminus T_j} [s_r \in K(\square)]$$
  
$$\leq 1 + \sum_{j=1}^{n-1} \sum_{\square \in T_j \setminus T_{j-1}} [s_r \in K(\square)]$$

 $\Rightarrow$  expected time for history searches is proportional to (n plus) the expected number  $\sum_{r=1}^{n-1} K_r$  of conflicts that appear during the algorithm.

14

13

## Analysis of Find (II)

Configuration spaces ⇒

$$\sum_{r=1}^{n-1} K_r \leq \sum_{r=1}^{n-1} (k_1 - k_2 + k_3)$$

$$\leq d(n-1)t_1 + d(d-1)n \sum_{r=1}^{n-1} \frac{t_{r+1}}{r(r+1)} - d^2 \sum_{r=1}^{n-1} \frac{t_{r+1}}{r+1}$$

$$= O(n \log n).$$

because

$$t_{r+1} = E(|T_r|) = O(r+1).$$

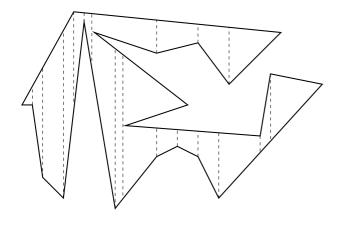

### Trapezoidal Map - Conclusion

Given a set S of n nonintersecting segments in the plane, its trapezoidal map T(S) can be computed in time

$$O(n \log n)$$
.

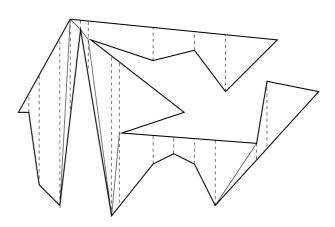

(The assumption that segment endpoints have different x-coordinates can be achieved by comparing them lexicographically.)

# Special Case: S forms simple polygon P

# Trapezoidal Map → Triangulation (I)

**Step 1:** Within each trapezoid, connect the two polygon vertices

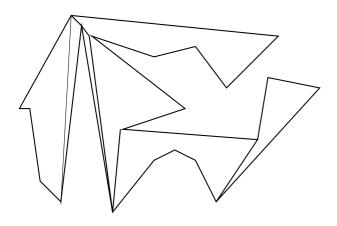

17

18

# Trapezoidal Map → Triangulation (II)

# **Step 2:** Triangulate the resulting x-monotone polygons separately, in total time O(n) (Exercise)

# A fast method for the special case (I)

Runtime will be  $O(n \log^* n)$ .

• 
$$\log^{(h)} n := \underbrace{\log \log \ldots \log n}_{h \text{ times}}$$

$$\bullet \ \log^{\star} n := \max\{h \mid \log^{(h)} n \geq 1\}$$

• Example: 
$$\log^*(2^{65536}) = 5 \Rightarrow \log^* n < 5$$
 "for all"  $n$ .

#### **Definition:**

$$N(h) := \lceil \frac{n}{\log^{(h)} n} \rceil, \quad 0 \le h \le \log^* n.$$

## A fast method for the special case (II)

Generalized history management: keep several histories and for each  $p \in P$  a pointer to the 'history in charge'.

Analysis of the fast method (I)

- **Split** and **Merge** proceed as before in expected time O(n)
- Find will be faster on average, but we have
- $\log^* n$  additional **Trace** steps

22

# Analysis of Find (I)

In phase h, every trapezoid traced during the history search corresponds to a trapezoid that

- has been present in the beginning of phase h or was created during phase h
- ullet is in conflict with a segment inserted in phase h

 $\Rightarrow$  expected cost of history search is at most proportional to  $n + K_h$ ,

$$K_h := \sum_{r=N(h-1)+1}^{N(h)} \sum_{\Box \in T_r \setminus T_{r-1}} |K(\Box) \cap S_{N(h)}|.$$

### Analysis of Find (II)

For fixed  $X := S_{N(h)}$ ,  $E(K_h)$  is the expected number of conflicts appearing in steps N(h-1)+1 to N(h) when T(X) is computed.

$$i := N(h-1) + 1, \quad j := N(h) - 1.$$

Configuration spaces analysis ⇒

$$E(K_h) \leq \sum_{r=i}^{j} (k_1 - k_2 + k_3)$$

$$\leq \frac{d(j+1-i)}{i} t_i + d(d-1)(j+1) \sum_{r=i}^{j} \frac{t_{r+1}}{r(r+1)} - d^2 \sum_{r=i}^{j} \frac{t_{r+1}}{r+1}.$$

21

# Analysis of Find (III)

Recall:

$$t_{r+1} = O(r+1).$$

Then

$$\begin{split} E(K_h) &= O(N(h) - N(h-1)) + \\ &O\left(N(h) \sum_{r=N(h-1)+1}^{N(h)-1} \frac{1}{r}\right) \\ &= O\left(N(h) + N(h) \log \frac{N(h)}{N(h-1)}\right) \\ &= O\left(N(h) + N(h) \log^{(h)} n\right) \\ &= O(n). \end{split}$$

(This also holds for a random set  $S_{N(h)}$  and for the last insertion phase  $(i = N(\log^* n) + 1, j = n - 1)$ .) The total cost for **Find** over all h is then  $O(n \log^* n)$ .

### Analysis of **Trace** (I)

The expected cost  $T_h$  of tracing S through  $T_{N(h)}$  is at most proportional to the expected number of conflicts between trapezoids in  $T_{N(h)}$  and segments in S, which is

$$\frac{1}{\binom{n}{N(h)}} \sum_{R \subseteq S, |R| = N(h)} \sum_{y \in S \setminus R} |\{\Box \in T(R) \mid y \in K(\Box)\}|.$$

Up to a missing factor of d/N(h) this is exactly the bound for the expected number  $K_{N(h)}$  of new conflicts when  $s_{N(h)}$  is inserted that we derived from the *configuration spaces*.

26

25

### Analysis of **Trace** (II)

	configuration spaces	here
$k_1$	$\frac{d}{r}(n-r)t_r$	$(n-r)t_r$
$k_2$	$\frac{d}{r}(n-r)t_{r+1}$	$(n-r)t_{r+1}$
<i>k</i> <sub>3</sub>	$\frac{d^2}{r(r+1)}(n-r)t_{r+1}$	$\frac{d}{r+1}(n-r)t_{r+1}$

Setting r = N(h), we obtain  $T_h = k_1 - k_2 + k_3$  as

$$T_{h} \leq (n - N(h))t_{N(h)} - (n - N(h))t_{N(h)+1} + \frac{d}{N(h)+1}(n - N(h))t_{N(h)+1}$$

$$= O\left(n(t_{N(h)} - t_{N(h)+1}) + n\right)$$

$$= O(n).$$

because  $t_{N(h)} \leq t_{N(h)+1}$ .

The total cost for **Trace** over all h is then  $O(n \log^* n)$ .

## Fast Trapezoidal Map – Conclusion

Given a simple polygon P with n vertices in the plane, its trapezoidal map T(P) can be computed in time

$$O(n \log^* n)$$
.

(This is not optimal, because Chazelle has given a (rather complicated) O(n) algorithm for the problem.)
